Abstract

Many times we need to plot 3-D functions e.g., in many scientific experiments. To plot the 3-D functions on 2-D screen it requires some kind of mapping. Though OpenGL, DirectX etc 3-D rendering libraries have made this job very simple, still these libraries come with many complex pre-operations that are simply not intended, also to integrate these libraries with any kind of system is often a tough trial. This article presents a very simple method of mapping from 3-D to 2-D, that is free from any complex pre-operation, also it will work with any graphics system where we have some primitive 2-D graphics function. Also we discuss the inverse transform and how to do basic computer graphics transformations using our coordinate mapping system.

1. Introduction

We have a function $f: \mathbb{R}^2 \rightarrow \mathbb{R}$, and our intention is to draw the function in 2-D plane. The function $z = f(x, y)$ is a 2-variable function and each tuple $(x, y, f(x, y)) \in \mathbb{R}^3$. Let's say we want to graphically plot f onto computer screen using a primitive graphics library (like Turbo C graphics), which supports only the basic putPixel (to draw a pixel in 2-D screen) -like 2-D rendering function, but no 3-D rendering; i.e., our graphics library's putPixel's domain is \mathbb{R}^2 and it's not \mathbb{R}^3 .

Hence in order to draw the function 'f' using our graphics library, we must design a coordinate conversion system, that will provide us with a function that will take as input 3-tuples $(x, y, f(x, y))$ and produce as output a 2-tuple (x', y') that can be directly passed to our graphics library to plot it onto the screen, but with 3-D look & feel. As we discussed, it's essential that we have a simple coordinate mapping system that maps \mathbb{R}^3 to \mathbb{R}^2 and still

gives us a hypothetical feeling of drawing 3-D functions. It's very easy to find such a map, i.e., a function h that maps from \mathbb{R}^3 to \mathbb{R}^2 , i.e., $h: \mathbb{R}^3 \rightarrow \mathbb{R}^2$ and in this paper we try to find such a simple map.

2. Proposed approach

We have a pictorial representation (Figure – 1) of our 3-D to 2-D mapping system:

Figure 1. Basic Model of a simple 3-D to 2-D mapping system

But, how the function f should look like after mapping and plotting? Here we simulate the 3rd coordinate (namely Z) in our 2-D x - y plane. We perform the logical to physical coordinate transform and everything by the map function h , which will basically turn out to be a 3×2 matrix. The basic mapping technique is shown in figure-2, which we are shortly going to explain.

$(0, 0)$

Figure 2. The basic coordinate mapping (w, h) If we have our Origin O at (x_0, y_0) screen coordinate, we have,

$$\begin{aligned} x' &= x_0 + y - x \cdot \sin(\theta) \\ y' &= y_0 - z + x \cdot \cos(\theta) \end{aligned} \quad (1)$$

i.e., we have our 3-D to 2-D transformation matrix:

$$M_{3 \times 2} = \begin{bmatrix} -\sin(\theta) & \cos(\theta) \\ 1 & 0 \\ 0 & -1 \end{bmatrix} \quad (2)$$

Again we have shifting (change of origin) by the matrix $O_{2D} = [x_0, y_0]$, so that we have following, $O_{2D} + P_{3D} \times M_{3 \times 2} = P_{2D}$, where \times denotes matrix multiplication and $+$ denotes matrix addition, the 3-tuple $P_{3D} = [x \ y \ z]$, the 2-tuple $P_{2D} = [x' \ y']$ i.e.,

$$\begin{matrix} 1 \times 2 & 1 \times 3 & 3 \times 2 & 1 \times 2 \\ \text{matrix} & \text{matrix} & \text{matrix} & \text{matrix} \end{matrix} \quad [x_0 \ y_0] + [x \ y \ z] \begin{bmatrix} -\sin\theta & \cos\theta \\ 1 & 0 \\ 0 & -1 \end{bmatrix} = [x' \ y'] \quad (3)$$

By default we keep the angle between X -axis & Z -axis $= \theta = \pi/4$, that one can change if required, but with the following inequality strictly satisfied: $0 < \theta < \pi/2$.

One can optionally use a compression factor to control the dimension along Z -axis by a compression factor ρ_z and slightly modifying the equations:

$$\begin{aligned} x' &= x_0 + y - x \cdot \sin(\theta) \\ y' &= y_0 - \rho_z \cdot z + x \cdot \cos(\theta) \end{aligned} \quad (4)$$

Obviously, $0.0 < \rho_z < 1.0$

By default we take $\rho_z = 1.0$

3. Sample Output Surfaces drawn using the above mapping:

Following surfaces (figure-3 and figure-4) are drawn in Turbo C++ version 3.0 (BGI graphics) using the above simple 3-D to 2-D mapping:

Figure 3. Sine function drawn in TurboC++ Ver 3.0 (BGI Graphics) using 3-D to 2-D mapping

Figure 4. Sync function drawn in TurboC++ Ver3.0 (BGI Graphics) using the 3-D to 2-D mapping

4. Inverse Transformation - Obtaining original 3-D coordinate from the transformed 2-D coordinate

Here, our transformation function (matrix) is:

$$\begin{aligned} x' &= x_0 + y - x \cdot \sin(\theta) \\ y' &= y_0 - z + x \cdot \cos(\theta) \end{aligned} \quad (5)$$

As we can see, it is impossible to re-convert and obtain the original set of coordinates, namely (x, y, z) , because we have 3 unknowns and 2 equations. So, in order to be able to get the original coordinates back, we at least need to store 3 tuples as result of the transformation, for instance, $(x, y, z) \rightarrow (x', y', z)$, the z -coordinate being stored only to get the inverse transform of the form $(x', y', z) \rightarrow (x, y, z)$ and the (x', y') pair is used to plot the point. So, in order to get the inverse transformation, we need to solve the equations for x, y , since we already know z , we have 2-equations and 2 unknown variables:

$$\begin{aligned} y - x \cdot \sin(\theta) &= x' - x_0 \\ x \cdot \cos(\theta) &= y' - y_0 + z \end{aligned} \quad (6)$$

Solving the above 2 equations we get,

$$\begin{aligned} x &= (y' - y_0 + z) \cdot \sec(\theta) \\ y &= x' - x_0 + (y' - y_0 + z) \cdot \tan(\theta) \end{aligned} \quad (7)$$

Put it in another way, our transformation matrix is a 3×3 matrix

$$M_{3 \times 3} = \begin{bmatrix} -\sin(\theta) & \cos(\theta) & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix} \quad (8)$$

Since a non-square matrix, no question of existence of its inverse. So, in order to be able to get the inverse transform as well, we need a 3×3 invertible square matrix, e.g.,

$$M_{3 \times 3} = \begin{bmatrix} -\sin(\theta) & \cos(\theta) & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix} \quad (9)$$

with

$$\begin{aligned} \text{Det}(M_{3 \times 3}) &= \det \begin{bmatrix} -\sin(\theta) & \cos(\theta) & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix} \\ &= 1 \cdot \begin{vmatrix} -\sin(\theta) & \cos(\theta) \\ 1 & 0 \end{vmatrix} = -\cos(\theta) \end{aligned} \quad (10)$$

Now, $0 < \theta < \pi/2$, hence $\cos(\theta) \neq 0$, hence $\text{Det}(M_{3 \times 3}) \neq 0$ and the inverse exists.

$$\begin{aligned} [x_0 \ y_0 \ 0] + [x \ y \ z] \begin{bmatrix} -\sin(\theta) & \cos(\theta) & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix} &= [x' \ y' \ z] \\ \begin{matrix} 1 \times 3 & 1 \times 3 & 3 \times 3 & 1 \times 3 \\ \text{matrix} & \text{matrix} & \text{matrix} & \text{matrix} \end{matrix} & \end{aligned} \quad (11)$$

But, we have,

$$\text{Inv}(M_{3 \times 3}) = (M_{3 \times 3})^{-1} = \frac{\text{Adj}(M_{3 \times 3})}{\text{Det}(M_{3 \times 3})},$$

$$\text{Det}(M_{3 \times 3}) \neq 0$$

and

$$\text{Adj}(M_{3 \times 3}) = \begin{bmatrix} 0 & -\cos(\theta) & 0 \\ -1 & -\sin(\theta) & 0 \\ -1 & -\sin(\theta) & -\cos(\theta) \end{bmatrix} \quad (12)$$

Hence,

$$\text{Inv}(M_{3 \times 3}) = M_{3 \times 3}^{-1} = \begin{bmatrix} 0 & 1 & 0 \\ \sec(\theta) & \tan(\theta) & 0 \\ \sec(\theta) & \tan(\theta) & 1 \end{bmatrix} \quad (13)$$

Here $\cos(\theta) \neq 0$

So, the inverse transform is:

$$[x \ y \ z] \begin{bmatrix} -\sin(\theta) & \cos(\theta) & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix} = [x' \ y' \ z'] - [x_0 \ y_0 \ 0]$$

$$\therefore [x \ y \ z] = [x' - x_0 \ y' - y_0 \ z'] \begin{bmatrix} 0 & 1 & 0 \\ \sec(\theta) & \tan(\theta) & 0 \\ \sec(\theta) & \tan(\theta) & 1 \end{bmatrix}$$

$$= [(y' - y_0 + z) \cdot \sec(\theta) \quad x' - x_0 + (y' - y_0 + z) \cdot \tan(\theta) \quad z] \quad (14)$$

This exactly matches with our previous derivation.

5. Rotation and affine transformations

A point in 3-D, after being mapped to 2-D screen, following the above mapping procedure, may be required to be transformed using standard computer graphics transformations (translation, rotation about an axis etc). But in order to undergo such a graphics transformation and to show the point back to the screen after the transformation, it needs to go through the following steps in our previously-described coordinate mapping system:

- First obtain the inverse coordinate transformation to obtain the original 3-D coordinates from the mapped 2-D coordinates
- Multiply the 3-D coordinate matrix by proper graphics transformation matrix in order to achieve graphical transformation.
- Use the same 3-D to 2-D map again to plot the point onto the screen.

These steps can be mathematically represented as:

- $P_{3D} = P_{2D} \times (M_{3X3})^{-1}$
 - $P_{3D}' = P_{3D} \times T_{3X3}$
 - $P_{2D}' = P_{3D}' \times M_{3X3}$
- (15)

Or, by a single-line expression,

$$P_{2D}' = ((P_{2D} \times (M_{3X3})^{-1}) \times T_{3X3}) \times M_{3X3} \quad (16)$$

Here, as before \times denotes matrix multiplication, and T_{3X3} denotes the traditional graphics transformation matrix.

But, since we know the fact that matrix multiplication is associative, we have,

$$\begin{aligned} P_{2D}' &= ((P_{2D} \times M_{3X3}^{-1}) \times T_{3X3}) \times M_{3X3} \\ &= P_{2D} \times M_{3X3}^{-1} \times T_{3X3} \times M_{3X3} \\ &= P_{2D} \times (M_{3X3}^{-1} \times T_{3X3} \times M_{3X3}) \end{aligned} \quad (17)$$

$$\therefore P_{2D}' = P_{2D} \times M'$$

$$\text{where } M' = M_{3X3}^{-1} \times T_{3X3} \times M_{3X3}$$

So, using this simple technique we can escape the 3 successive matrix multiplications every-time a point on screen needs to be transformed – instead what we can simply do is pre-compute

$$M' = M_{3X3}^{-1} \times T_{3X3} \times M_{3X3}. \quad (18)$$

This matrix M' is needed to be computed once for a given graphics transformation (e.g., rotation about an axis) and applied to all points on the screen, so that using a single matrix multiplication thereafter any point on the screen can undergo graphics transformation, by, $P_{2D}' = P_{2D} \times M'$, where P_{2D} represents the point mapped before transformation T_{3X3} and P_{2D}' is the point re-mapped after the transformation, as obvious.

Hence, using the above tricks we are able to make the transformation more computationally efficient.

Moreover, if a transformation is needed to be applied simultaneously, we can use the property $M_{3 \times 3}^{-1} \times (T_{3 \times 3})^n \times M_{3 \times 3} = (M_{3 \times 3}^{-1} \times T_{3 \times 3} \times M_{3 \times 3})^n$, where $(T_{3 \times 3})^n$ denotes (n times, n is a positive integer) simultaneous matrix multiplication of $T_{3 \times 3}$. Let's say we have already undergone a $T_{3 \times 3}$ transformation, so that we have already computed $M' = M_{3 \times 3}^{-1} \times T_{3 \times 3} \times M_{3 \times 3}$, and let's say that we also have frequent simultaneous $(T_{3 \times 3})^n$ transformation. In order to undergo a $(T_{3 \times 3})^n$ transformation, we first need to compute the matrix $(T_{3 \times 3})^n$, then we need to compute our new matrix $M'' = M_{3 \times 3}^{-1} \times (T_{3 \times 3})^n \times M_{3 \times 3}$, so we need total n + 2 matrix multiplications, every-time we want a $(T_{3 \times 3})^n$ transform, for each n.

But if we have computed $M_{3 \times 3}^{-1} \times T_{3 \times 3} \times M_{3 \times 3}$ initially, here the trick is that we can reuse this it to compute our new matrix in the following manner:

$$\begin{aligned} M'' &= M_{3 \times 3}^{-1} \times (T_{3 \times 3})^n \times M_{3 \times 3} \\ &= (M_{3 \times 3}^{-1} \times T_{3 \times 3} \times M_{3 \times 3})^n = (M')^n \end{aligned} \quad (19)$$

Here we need not compute $(T_{3 \times 3})^n$ and M'' every-time, instead we need to compute $(M')^n$ only (that can be incremental multiplication to increase efficiency).

6. Conclusions

This article presented a very simple method of mapping from 3-D to 2-D, that is free from any complex pre-operation. The proposed technique works with any graphics system where we have some primitive 2-D graphics function. We also discussed the inverse transform and how to do basic computer graphics transformations using our coordinate mapping system.
